DATA DASHBOARD AND CONSULTANT ROSTER

Project 1: Data Dashboard Project

PlanCatalyst would like to develop a *Data Dashboard* as a central feature of the redesigned PlanCatalyst website, to showcase our capabilities data-informed decision-making and to serve as a resource for development practitioners and partners. The dashboard is intended to offer publicly accessible, interactive insights into country-level indicators across key development themes—including SDG progress, demographic trends, climate vulnerability (ND-GAIN), financial inclusion, governance, and gender equity. This tool will showcase PlanCatalyst's analytical capabilities and support our stakeholders by providing localized, policy-relevant data.

From a technical perspective, we envision two possible implementation paths: either a fully custom-built, integrated dashboard leveraging real-time or scheduled data retrieval; or an embedded solution using platforms such as Tableau or Power BI with a seamless user interface. In both cases, the dashboard must be capable of refreshing data on a six-monthly, annual, or ad hoc basis, and should retrieve indicators from publicly available APIs (e.g., World Bank, UN datasets). A key component will also involve data analysis to develop and present a composite index that ranks or scores countries based on selected indicators. The solution should support geographic navigation (e.g., an interactive map), filtering by region or theme, and comparative views. The dashboard should be deployable on PlanCatalyst's website, currently hosted on Wix. PlanCatalyst has strong internal expertise in data analysis, indicator mapping, and index construction, and our team would work closely with developers throughout the design and implementation phases to inform the technical and analytical approach.

Project 2: AI-Enabled Consultant Roster System

We would like to develop an automated, AI-supported consultant roster to help Plan International streamline the identification and deployment of external technical experts for commercial contracting opportunities. This system will move away from current manual, spreadsheet-based processes and toward a centralized, automated solution. The goal is to enable rapid, AI-powered intake and categorization of consultant CV data (e.g., sector expertise, regional experience, availability), support fast consultant matching for bids, and ensure secure, scalable, and compliant management of consultant profiles.

From a technical standpoint, one option is to build the system entirely within the Microsoft 365 enterprise ecosystem—leveraging tools such as SharePoint, Microsoft Lists, Power Automate, Outlook integrations, and AI Builder/Azure AI for CV parsing and workflow automation. However, depending on technical feasibility, user experience needs, or data processing limitations, we could also consider hybrid or alternative approaches—including third-party platforms or a lightweight custom-coded solution (e.g., a web-based application with secure database and API-driven ingestion). Regardless of platform, the system must support multiple consultant intake channels (webforms, referrals, email), enable AI-powered parsing and tagging of profile data, and allow for internal and selectively controlled external access.

Additional requirements include compliance with data privacy regulations (e.g., GDPR), including automated consent workflows and user data controls; the ability to refine the AI model instructions; and the flexibility to scale in the future to other Plan offices through service-based versions of the system.
